

AI product manager — candidate assignment

Role: AI Product Manager

Estimated effort: 2–3 days (with AI agent assistance encouraged)

Submission format: Working prototype

About this assignment

At Signit, we ship AI-powered products that solve real problems for real users. This assignment simulates the kind of work you'd do on day one: take an ambiguous, high-stakes problem, break it into something buildable, design a solution that users actually want to use, and deliver a working prototype — all with AI tools as your copilot.

We are not looking for wireframes, Figma mockups, or clickable prototypes. We want a **fully functional, interactive prototype** built using any AI-assisted development tool of your choice (Cursor, Lovable, Bolt, Replit Agent, Claude, Antigravity, etc.). Your product thinking, UX instincts, and innovation will be what separates great from good.

You can submit multiple prototypes if you would live, but highlight the one you think is the best. You can deliver an online hosted link or though a Github repo with instructions on how to run it “we can run anything locally, no worries”

The problem

Context

Enterprise organizations deal with thousands of contracts every year — vendor agreements, NDAs, SaaS subscriptions, employment contracts, partnership terms, and more. These contracts contain obligations, deadlines, auto-renewal traps, penalty clauses, and compliance requirements buried deep inside dense legal language.

Today, most companies manage this through a painful combination of:

- Shared drives full of PDFs nobody reads after signing
- Spreadsheets tracking renewal dates (often outdated)
- Legal teams manually reviewing contracts when something goes wrong
- People discovering unfavorable terms only after they've been triggered
- Zero visibility into what the organization has actually committed to across all its contracts

The result: companies lose money to forgotten auto-renewals, miss critical deadlines, accept contradictory terms across vendors, and have no way to answer simple questions like *"which of our vendor contracts have a liability cap below \$1M?"* or *"what contracts are up for renewal in the next 90 days that we should renegotiate?"*

The challenge

Design and build a **post-signature contract intelligence system** — an AI-powered product that turns signed contracts from static, forgotten documents into a live, queryable, actionable knowledge base for the organization.

This is deliberately **not** about e-signatures or contract authoring. This is about what happens **after** a contract is signed — which is where most of the value (and risk) actually lives.

Who are the users?

You must serve at least these three personas (you may add more if your solution calls for it):

1. **The legal counsel** — Needs to quickly assess risk exposure across the portfolio, compare terms across similar contracts, and catch problematic clauses before they become liabilities. Currently spends hours manually searching through documents.
2. **The procurement/operations manager** — Manages vendor relationships and renewals. Needs to know what's coming up, what terms they agreed to, and where they have leverage to renegotiate. Currently relies on calendar reminders and memory.
3. **The executive (CFO/COO)** — Wants a strategic view: total contractual commitments, concentration risk, upcoming financial obligations, and compliance posture. Currently gets this information weeks late, if at all.

What we're evaluating

1. Problem decomposition and product thinking (30%)

- How well do you understand the real user pain points vs. surface-level symptoms?
- Have you identified the highest-leverage problems to solve first?
- Do your decisions reflect an understanding of what's technically feasible with AI today vs. what's aspirational?
- Have you made deliberate trade-offs and can you articulate why?

2. Solution design and UX innovation (35%)

This is the most heavily weighted criterion. We are looking for:

- **Interaction design that feels new.** Generic dashboards with tables and filters are not interesting. How does a user *actually* interact with a living contract knowledge base? What paradigms make complex legal information accessible to non-lawyers?
- **AI-native UX.** Don't bolt AI onto a traditional interface. Think about what interactions become possible when the system *understands* the content. How do you handle AI confidence and uncertainty? How does the user build trust in AI-extracted information?
- **Multi-persona coherence.** The same underlying data serves very different needs. How do you design for this without building three separate products?
- **Edge cases and real-world messiness.** Contracts come in different formats, languages, and structures. What happens when the AI is wrong? When a contract is ambiguous? When data is missing?
- **Progressive disclosure.** How do you surface the right level of detail at the right moment? A CFO and a lawyer need very different depths of information from the same contract.

3. Functional prototype (25%)

- Is it a working, interactive application (not a static mockup)?
- Does it demonstrate the core interactions and flows you've designed?
- Is the UI polished enough to communicate your design intent clearly?
- Have you used realistic sample data that makes the experience feel tangible?
- Does it handle state, navigation, and user flows in a way that feels like a real product?

4. AI integration and innovation (10%)

- If your prototype includes live AI features (e.g., actual contract parsing, natural language queries, AI-generated summaries), that's a strong bonus — but not required
- At minimum, we expect the prototype to simulate AI behavior convincingly enough to demonstrate how the experience would work
- Bonus points for creative use of AI in the product itself or innovative use of AI tools in your build process

Deliverables

Deliverable 1: Product document

A concise document (max 5 pages) covering:

1. **Problem analysis** — Your understanding of the problem space. What are the real pain points? What did you learn that wasn't obvious from the brief? What assumptions are you making?

2. **Solution overview** — What are you building and why? What's your core insight or thesis about how to solve this? What did you deliberately leave out and why?
3. **User flows and interaction model** — How does each persona use the system? What are the key moments of interaction? Walk us through 2–3 core scenarios.
4. **AI architecture (conceptual)** — What AI capabilities does your solution rely on? How do you handle accuracy, confidence, and failure modes? You don't need to build the AI pipeline — just show you've thought about it seriously.
5. **What you'd do with more time** — If this were a real project, what would phase 2 look like?

Deliverable 2 “Most important”: Working prototype “you can provide multiple prototypes as well”

A fully functional, interactive prototype that demonstrates your core solution. Requirements:

- Must be runnable (deployed URL, or local setup with clear instructions)
 - Must use realistic, representative sample data (not lorem ipsum)
 - Must demonstrate at least 3 distinct user flows
 - Must feel like a real product someone could test, not a proof of concept
 - Built using any AI-assisted development tool you prefer
-

What we don't want

- A feature-list product that tries to do everything and does nothing well
 - A generic dashboard with charts and tables that could apply to any domain
 - A ChatGPT-in-a-box where the only interaction is typing into a chat window
 - Wireframes, Figma files, or non-functional prototypes
 - A copy of an existing product (we will check)
-

Practical notes

- **Timeline:** You have around 3 calendar days from receiving this assignment. We know you have a life — we're testing quality of thinking, not hours worked.
 - **AI tools:** Use whatever AI tools you want. We expect you to. Part of what we're evaluating is how effectively you leverage AI to build faster and better. Document which tools you used.
 - **Sample data:** Create your own realistic sample contracts and data. The quality and realism of your test data is part of the evaluation.
-

A note on what great looks like

The best submissions we've seen in similar assessments share a few traits:

- They pick a sharp angle on the problem rather than trying to boil the ocean
- They introduce at least one interaction pattern that makes us say "oh, that's clever"
- They use AI in the product in a way that feels natural, not forced
- They demonstrate deep empathy for the users — you can tell the candidate actually thought about what it feels like to use the product
- The prototype feels surprisingly complete for the timeframe, because the candidate used AI tools effectively to build faster

Good luck. We're genuinely excited to see what you build.
